

① DOM in JS and their Needs:

* DOM (Document Object Model) is when a webpage is loaded in the browser, the browser converts the HTML document into a tree like object structure.

Needs

- change text content
- change HTML content
- change CSS style
- Add new element
- change attributes.

② HTML	DOM
* HTML is the markup code used to create a webpage.	* DOM is the object representation of that webpage
* Written using HTML tags.	* Represented as objects.

③ Document object in JS:

* The Document object represents the HTML document.

* It provides methods to select and manipulate HTML elements.

④ DOM selectors:

* DOM selectors are used to select or access HTML elements from JS.

* JS provides multiple methods to select elements.

Important Selectors :

- (i) getElementById()
- (ii) getElementsByClassName()
- (iii) getElementsByTagName()
- (iv) querySelector()
- (v) querySelectorAll()

⑤	getElementById()	querySelector()
	* Selects an Element by ID	* Selects an element using a CSS selector.
	* Returns one element.	* Return the first matching element
	* Does not need #	* Used #. for ID

⑥	querySelector()	querySelectorAll()
	* Selects the first matching element.	* Selects all matching elements.
Eg document.querySelector(".para")		Eg: document.querySelectorAll(".para");

⑦	textContent	innerText	innerHTML
	* changes all the text content	* changes visible text	* changes HTML content
	element.textContent = "Hello";	element.innerText = "Hello";	element.innerHTML = "Hello";

⑧ We can modify CSS styles using the "style" Property.

Example:

```
const title = document.getElementById("title");  
title.style.color = "Black";  
title.style.backgroundColor = "Red";  
title.style.fontSize = "40px";
```
